32 Abstract

33 Objectives

34 Recent 2022 SARS-CoV-2 Omicron variants, have acquired resistance to most neutralizing anti-
35 Spike monoclonal antibodies authorized, and the BQ.1.* sublineages are notably resistant to all
36 authorized monoclonal antibodies. Polyclonal antibodies from individuals both vaccinated and
37 recently recovered from Omicron COVID-19 (VaxCCP) could retain new Omicron neutralizing
38 activity.

39 Methods

40 Here we reviewed BQ.1.* virus neutralization data from 920 individual patient samples from 43
41 separate cohorts defined by boosted vaccinations with or without recent Omicron COVID-19, as
42 well as infection without vaccination.

43 Results

44 More than 90% of the plasma samples from individuals in the recently (within 6 months) boosted
45 VaxCCP study cohorts neutralized BQ.1.1, and BF.7 with 100% neutralization of WA-1, BA.4/5,
46 BA.4.6 and BA.2.75. The geometric mean of the geometric mean 50% neutralizing titers (GM
47 (GMT₅₀) were 314, 78 and 204 for BQ.1.1, XBB.1 and BF.7, respectively. Compared to VaxCCP,
48 plasma sampled from COVID-19 naïve subjects who also recently within 6 months received at
49 least a third vaccine dose had about half of the GM (GMT₅₀) for all viral variants.

50 Conclusions

51 Boosted VaxCCP characterized by either recent vaccine dose or infection event within 6 months
52 represents a robust, variant-resilient, passive immunotherapy against the new Omicron BQ.1.1,
53 XBB.1 and BF.7 variants.

77 Introduction

78 In immunocompromised (IC) patients both passive immunotherapies and small molecule antivirals
79 are often necessary to treat COVID-19 or eliminate persistently high SARS-CoV-2 viral load.
80 Chronic, persistent viral loads increase both transmission and mutation risk, and prevent
81 administration of the required immunosuppressive/antineoplastic therapies(1). Small molecule
82 antivirals have not been formally validated for IC patients, who often have contraindications, and
83 the convergent evolution of the Omicron variant of concern (VOC) has led to inefficacy of all the
84 anti-Spike monoclonal antibodies (mAbs) authorized so far for both treatment or prevention, e.g.
85 in the highly prevalent BQ.1.* sublineages(2). The other rapidly growing XBB.* and BF.7
86 sublineages are also highly resistant to anti-Spike mAbs(3). Polyclonal plasma from individuals
87 who are both vaccinated and had COVID-19 (VaxCCP) has more than ten times the antibody
88 levels capable of neutralizing pre-Omicron variants as well as Omicron variants BA.1 through
89 BA.4/5(4, 5). Polyclonal COVID-19 convalescent plasma (CCP) has thousands of distinct
90 antibody specificities of different isotypes, including many capable of SARS-CoV-2
91 neutralization. High-titer pre-Omicron CCP contains Omicron neutralizing activity despite being
92 collected before variant appearance(4, 5).

93
94 Given that CCP remains a recommended therapy for IC(1, 6, 7), we systematically reviewed recent
95 primary research for neutralization results against BQ.1.1 by plasma collected from vaccinated
96 subjects with or without COVID-19 or after recent Omicron infection alone.

97

98 Results

99 Ten articles were included (**Figure 1**) which contained virus neutralizations with WA-1, BQ.1.1,
100 BA.4/5, BA.4.6, XBB.1 and BF.7, assessed with either live authentic SARS-CoV-2 or SARS-
101 CoV-2 pseudovirus neutralization assays and represented data from 920 patients (**Supplementary**
102 **Table 1**). Qu *et al.* in the USA reported on Spring and Summer 2022 breakthrough infections with
103 BA.1 and BA.4/5 in two sampled cohorts with predominantly unvaccinated individuals, as well as
104 a third cohort of healthcare workers after a single monovalent booster vaccination in the Fall of
105 2021(8) (**Table 1**). Zou *et al.* in the USA in the Summer and Fall of 2022 sampled individuals who
106 had already received 3 mRNA BNT162b2 vaccinations with or without previous COVID-19, both
107 before and about 4 weeks after a 4th monovalent or bivalent vaccine booster vaccination(9). Miller
108 *et al.* also in the USA sampled both before the 3rd vaccination dose and about 4 weeks after
109 monovalent mRNA vaccination in the Fall of 2021, as well as with the 4th vaccine dose in the
110 Summer or Fall of 2022, with either monovalent or bivalent booster vaccinations in Fall of 2022
111 in those with no documented COVID-19(10). Cao *et al.* in China investigated BQ.1.1
112 neutralizations from plasma of 4 cohorts after 3 doses of CoronaVac (Fall 2021) without COVID-
113 19 or 2-12 weeks after BA.1, BA.2 and BA.5 infection(3). Planas *et al.* in France evaluated
114 GMT₅₀ in plasma from individuals both 4 and 16 weeks after a third monovalent mRNA vaccine
115 dose in the Fall of 2021 as well as 12 and 32 weeks after vaccine breakthrough BA.1/2 or BA.5
116 infection(11). Davis *et al.* in the USA sampled after the 3rd mRNA vaccine monovalent dose in the
117 Fall of 2021 and also after either a 4th monovalent mRNA dose or a bivalent (wild-type + BA.4/5)
118 vaccine dose in the Summer and Fall of 2022(12). Kurhade *et al.* in the USA also compared
119 GMT₅₀ after the 4th monovalent vaccine dose or 3 mRNA doses with the 4th the bivalent dose
120 without COVID-19 and also after bivalent boost with recent COVID-19(13). Wang *et al.* in the
121 USA compared GMT₅₀ after three vaccine doses, the 4th monovalent vaccine dose or 3 mRNA
122 doses with the 4th the bivalent dose without COVID-19, and also after 2-3 vaccine doses and recent

123 BA.2 breakthrough infection or 3-4 mRNA vaccine doses and recent BA.4/5 breakthrough
124 infection(14). Ito et al in Japan compared breakthrough infections after BA.2 and BA.5 after 2-3
125 doses of mRNA vaccines in the Spring and Summer of 2022(15). Akerman et al in Australia
126 characterized neutralizing antibodies in four groups 1) sampling one to three months after 3 doses
127 of mRNA vaccines with an Omicron infection in 2022; 2) sampling 3 months after 4 doses of
128 mRNA vaccine; 3) sampling 6 months after 3 doses of mRNA vaccine and 4) sampling 3-6 months
129 after last vaccine in a larger cohort who had the original WA-1 infection in early 2020 as well as
130 3 more doses of mRNA vaccine(16).

131
132 These diverse cohorts were assembled into 3 groups, 1) plasma after both 2-4 vaccine doses and
133 COVID-19 (VaxCCP); 2) plasma from subjects after administration of 3-4 vaccine doses (i.e.
134 boosted), but either self-reported as COVID-19-*naïve* or anti-nucleocapsid negative; and 3)
135 Omicron infection without vaccination (CCP) as well as participants sampled 6 to 11 months after
136 previous vaccine dose and before the booster vaccination. Boosted VaxCCP neutralized BQ.1.1,
137 XBB.1 and BF.7 with approximately 3 times the dilutional potency of the vaccine-only or 2-6
138 times CCP/pre-boost vaccination groups for all viral variants (**Table 2 and Figure 2**). Importantly,
139 while there was a 19-fold reduction in neutralization by boosted VaxCCP against BQ.1.1 compared
140 to WA-1, more than 90% of the boosted VaxCCP samples neutralized BQ.1.1 as well as XBB.1
141 and BF.7 (**Table 2 and Figure 2c**). Three cohorts within the boosted VaxCCP group were below
142 at 90% neutralization with one sampled late, 8 months after BA.1/2 breakthrough infection(11)
143 and the other two from a single study after BA.2 and BA.5 (**Supplementary Table 2 and 3**).
144 Except for the GMT (GMT₅₀) against XBB.1 at 78, the other viral variant neutralizations were in
145 the same range as pre-Alpha CCP neutralizing WA-1 (i.e., 311)(4). By comparison the large
146 randomized clinical trial which effectively reduced outpatient COVID-19 progression to
147 hospitalizations had a GMT₅₀ of 60 for WA-1 with pre-Alpha CCP(17). Boosted vaccinations at
148 3-4 doses without COVID-19, showed GM (GMT₅₀) of 118 for BQ.1.1, with only 6 of 23 cohorts
149 over 90% neutralizations, for 79% overall (i.e. 326 of 414 individuals). Four separate
150 studies(8),(13),(12),(10) characterized BQ.1.1 virus neutralizations with plasma after the new
151 bivalent (wild-type + BA.4/5) mRNA vaccine booster in the Fall of 2022, with 88% (103 of 117
152 samples) neutralization activity within 4 weeks of bivalent booster (**Supplementary Table 3**).

153
154 Many studies performed virus neutralizations on samples drawn before the 3rd or 4th vaccine dose
155 which were 6 to 11 months after last vaccine dose. The GM (GMT₅₀)'s for BQ.1.1 and BA.2.75
156 were about 6 times reduced compared to VaxCCP even though the fold reductions were similar
157 (**Figure 3, Table 2**). In agreement with lower GMT₅₀ for neutralizations was the low percent
158 neutralizing BQ.1.1 (63%), XBB.1 (50%), and BF.7 (75%) at 6 to 11 months after vaccination
159 (**Figure 3, Table 2 and Supplementary Table 3**).

160
161 Five studies used the lentiviral pseudovirus assays, with diverse Spike proteins cloned in, while
162 the other four were live virus assays using different cell types (**Supplementary Table 1**). Notably,
163 Planas *et al* employed the IGROV-1 cell type for better growth of Omicron sublineages(11). While
164 the single study fold reductions (FR) and percent neutralizations normalize the results between
165 studies, the GMT₅₀ can vary between studies even amongst the live authentic viral neutralization
166 studies (e.g., mNeonGreenTM reporter assays versus cytopathic effects)(9, 13). We sorted the live
167 authentic viral neutralizations from the pseudoviral neutralizations, plotting also the minimum and
168 maximums (**Supplementary Figures 1-3**). In general, the live authentic SARS-CoV-2

169 neutralization assays for VaxCCP appeared to have similar antibody neutralization levels, with the
170 single study by Cao et al(3) employing lentiviral pseudovirus with lower dilutional titers. In
171 contrast, the GMT₅₀ achieved with pseudoviral assays in the boosted vaccinations without COVID-
172 19 appeared slightly higher than the ones achieved with authentic virus.

173

174 Discussion

175 The FDA deemed CCP safe and effective for both immunocompetent and IC COVID-19
176 outpatients(6, 7, 18), and further extended its authorized use in the IC patient population in
177 December 2021(7, 18), at a time when oral antiviral therapy promised a no transfusion outpatient
178 solution and many anti-Spike mAbs were still effective.

179

180 Up until the present, CCP remained a backup bridge for IC patients, durable against the changing
181 variants and as a salvage therapy in seronegative IC patients. With the recent advent of Omicron
182 XBB.* and BQ.1.* defeating the remaining anti-Spike mAbs, boosted VaxCCP, recently collected
183 within the last 6 months of either a vaccine dose or SARS-CoV-2 is likely to be the only viable
184 remaining passive antibody therapy in the 2022-23 Winter for IC patients who have failed to make
185 antibodies after vaccination and still require B-cell depleting drugs or immunosuppressive therapy.
186 In a literature review of CCP from diverse VOC waves as well as boosted vaccinees and VaxCCP
187 up to BA-1, VaxCCP showed higher neutralization titers against Omicron at levels above 300
188 dilutional GMT₅₀⁴.

189

190 The accelerated evolution of SARS-CoV-2 VOCs has created the problem that the pharmaceutical
191 development of additional mAbs is not worth the effort and cost given their expected short useful
192 clinical life expectancy, so the anti-Spike mAb pipeline has remained stuck in 2022. High levels
193 of antibodies in donor plasma from both boosted vaccinations and COVID-19 convalescent plasma
194 (VaxCCP) neutralizing more than 93% of BQ.1.1 and BF.7, with XBB.1 at 89%. Recently collected
195 plasma within a 6 months window from those boosted vaccinees without prior documented
196 COVID-19 had a 20-30% reduction in neutralization percent for BQ.1.1 and XBB.1 with 10%
197 reduction for the others and a third of the GM (GMT₅₀) neutralizing antibody levels compared to
198 VaxCCP. In those vaccinated with last dose more than 6 months prior to sample collection, both
199 the neutralization percent and neutralizing antibody titers fell further, compared to the recently
200 boosted VaxCCP group. Four studies (Planas(11), Zou(9), Cao(3) and Kurhade(13)) had directly
201 comparative cohorts in the three groups which increases the robustness reduction in neutralizations
202 with the vaccine only or more than 6 months to last vaccine or infection event compared to
203 VaxCCP. The main limitation of our systematic review is the small number of studies reporting
204 virus neutralization with BQ.1.1 with most available as pre-preprints without peer-review yet.
205 However, we note that peer-review itself does not change GMT₅₀ or neutralization numbers and
206 the authors of these papers have considerable expertise in the topic.

207

208 Boosted VaxCCP has full potential to replace anti-Spike mAbs for passive antibody therapy of IC
209 patients against recent Omicron sublineages, in the meanwhile polyclonal IgG formulations can
210 be manufactured. VaxCCP qualification in the real-world will likely remain constrained on high-
211 throughput serology, whose correlation with GMT₅₀ is not perfect(19, 20). Nevertheless, the very
212 high prevalence (93%) of Omicron-neutralizing antibodies and the high GM (GMT₅₀) in recently
213 boosted VaxCCP reassure about its potency, and further confirm that exact donor-recipient VOC

214 matching is dispensable. Overall, our findings urge WHO to revise its guidelines and recommend
215 boosted VaxCCP for therapy of COVID-19 in IC patients.

216

217

218 [Search strategy and selection criteria](#)

219 On November 19, 2022 we initially searched PubMed, medRxiv and bioRxiv for manuscripts
220 reporting BQ.1.1 neutralization, using English language as a restriction. Search of bioRxiv with
221 same keywords now yields 17 records of which only 10 contained plasma viral neutralization data.
222 Search of medRxiv produced 3 records which did not have BQ.1.1 neutralizations. PubMed
223 retrieved 3 entries using (“BQ.1.1”) and (“neutralization”), one of which was focused on anti-
224 Spike mAb alone(2) and the other 2 were duplicates from bioRxiv(8, 12). Articles underwent
225 evaluation for data extraction by two assessors (DS and DF) with disagreements resolved by third
226 assessor (AC). Articles lacking plasma BQ.1.1 virus neutralizations were excluded. The process
227 of study selection is represented in the PRISMA flow diagram (**Figure 1**).

228

229 The type of viral assay (live or pseudovirus), time interval to blood sample, GMT₅₀, minimum and
230 maximum neutralizing 50% dilutional titer for WA-1 (pre-Alpha wild-type) and Omicron
231 sublineages BQ.1.1, BA.4/5, BA.4.6, BA.2.75, XBB.1 and BF.7 and number out of total that
232 neutralized Omicron were abstracted from study text, graphs and tables. Two studies (Wang(14)
233 and Qu(8)) reported BQ.1 and those were separate cohorts in addition to BQ.1.1. Prism v. 9.4
234 (GraphPad Software, San Diego, CA, USA) was used for data analysis. While all manuscripts
235 included neutralization data against WA-1, BQ.1.1, BA.4/5 and BA.2.75, only a subset of
236 manuscripts included neutralization data for BA.4.6, XBB.1 and BF.7 which were assembled for
237 relevance to present circulating variants. Historic early Omicron partial neutralization data on
238 variants like BA.1 or BA.2 were excluded because of the full set data with BA.4/5 and BA.2.75.

239

240 Statistical significance between log₁₀ transformed GMT₅₀ was investigated using Tukey’s test. The
241 multiple comparison test was a two-way ANOVA with Alpha 0.05 on log transformed GMT₅₀.
242 The log normal test was performed on WA-1, BQ.1.1, BA.4/5, BA.4.6, XBB.1 and BF.7 virus
243 GMT₅₀. Two studies(10, 11) reported the median titer rather than the GMT₅₀. Compiled data
244 abstracted from the published studies is available in the supplementary dataset.

331 **Table 1**

332 Synopsis of included studies, reporting plasma sources, epoch of sampling, region, time since
 333 vaccination/infection to plasma sampling, and sample size. The cohorts were split into three
 334 groups-1) boosted vaccinations and recent COVID-19 (VaxCCP), 2) boosted vaccines only
 335 without documented COVID-19 (Vac only) and 3) infection alone or pre-boostered sampling
 336 before 3rd or 4th vaccine dose (Infection only or pre-boost)

Study	Vaccine and COVID-19 history at sample time	Group	Time period of plasma sampling	Geography	Sampling time mean or median (min-max)	Sample number
Cao(3)	3xCorVac+BA.1 inf	VaxCCP	Spring 2022	China	5-7 weeks post hosp admit (42 weeks avg)	50
Cao(3)	3xCorVac +BA.2 inf	VaxCCP	Summer 2022	China	3-11 weeks post hosp admit (8 weeks mean)	39
Cao(3)	3xCorVac +BA.5 inf	VaxCCP	Summer/F all 2022	China	2-11 weeks (mean 5 weeks)	36

338 **Table 2**

339 GM (GMT₅₀) of plasma from three different sources against recent Omicron sublineages.

Neutralization virus	WA-1	BQ.1.1	BA.4/5	BA.4.6	BA.2.75	XBB.1	BF.7
Post COVID-19/vaccine (study cohorts)	12	16	14	7	9	9	4
GM (GMT ₅₀)	5876*	314	987	346	303	78	204
Fold reduction from WA-1	ref	19	6	17	19	75	32
Samples tested	294	237**	328	135	231	125	148
Samples neutralizing	285	221	326	135	230	111	146
Percent neutralizing	97	93	99	100	100	89	99
Boosted vaccine (study cohorts)	19	23	19	10	14	10	7
GM (GMT ₅₀)	3766	118	346	126	107	52	357
Fold reduction from WA-1	ref	32	11	30	35	72	12
Samples tested	384	414	384	206	261	217	158
Samples neutralizing	383	326	363	191	231	125	149
Percent neutralizing	100	79	95	93	89	58	94
Infection only or preboosted vaccine (study cohorts)	10	12	10	7	9	5	5
GM (GMT ₅₀)	870	47	96	103	57	23	110
Fold reduction from WA-1	ref	19	9	8	15	38	9
Samples tested	184	220	184	136	162	101	84
Samples neutralizing	182	139	144	104	104	50	63
Percent neutralizing	99	63	78	76	64	50	75

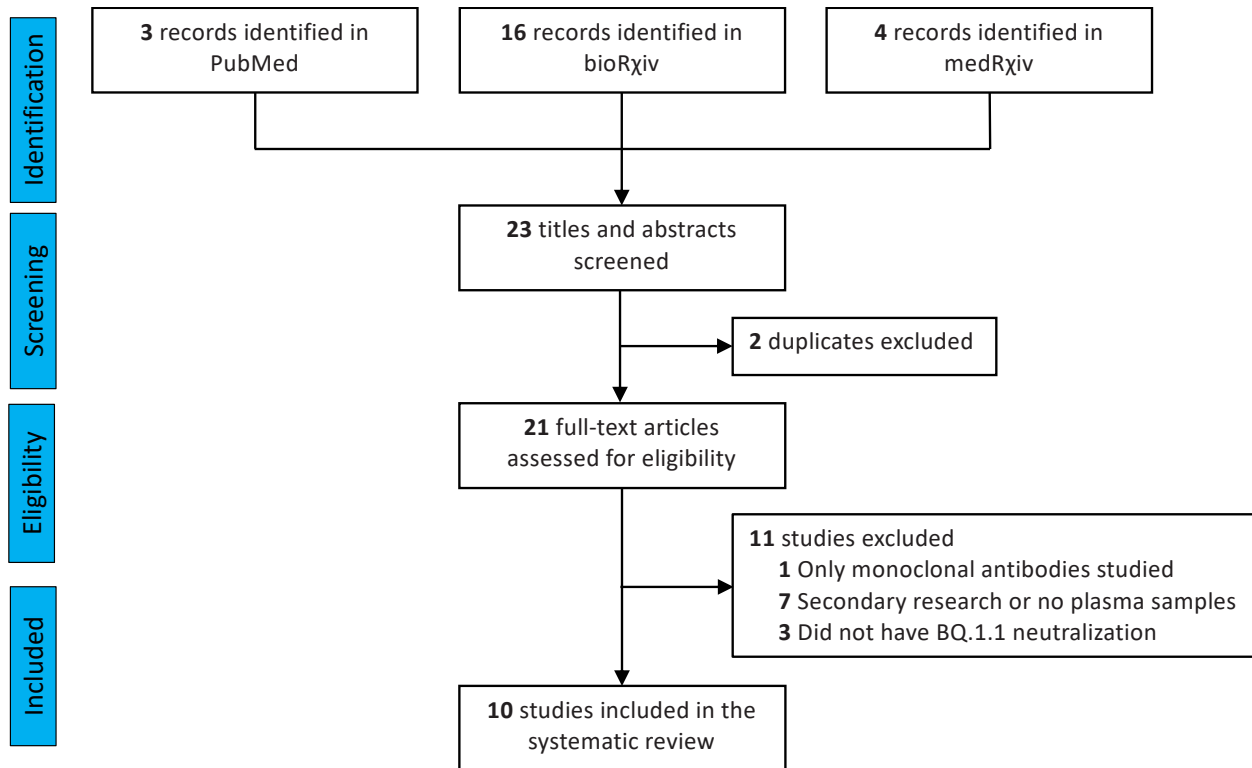

340 *Pre-Alpha CCP from 27 different studies had a GM (GMT₅₀) of 311 from 707 samples with 315
 341 or 45% neutralizing omicron BA.1(4).

342 ** percent neutralizations after CoronaVac and Omicron COVID-19 in the paper by Cao *et al*
 343 could not be retrieved from the manuscript. 237 samples from the 6 other cohorts were used for
 344 percent neutralization.

345

346

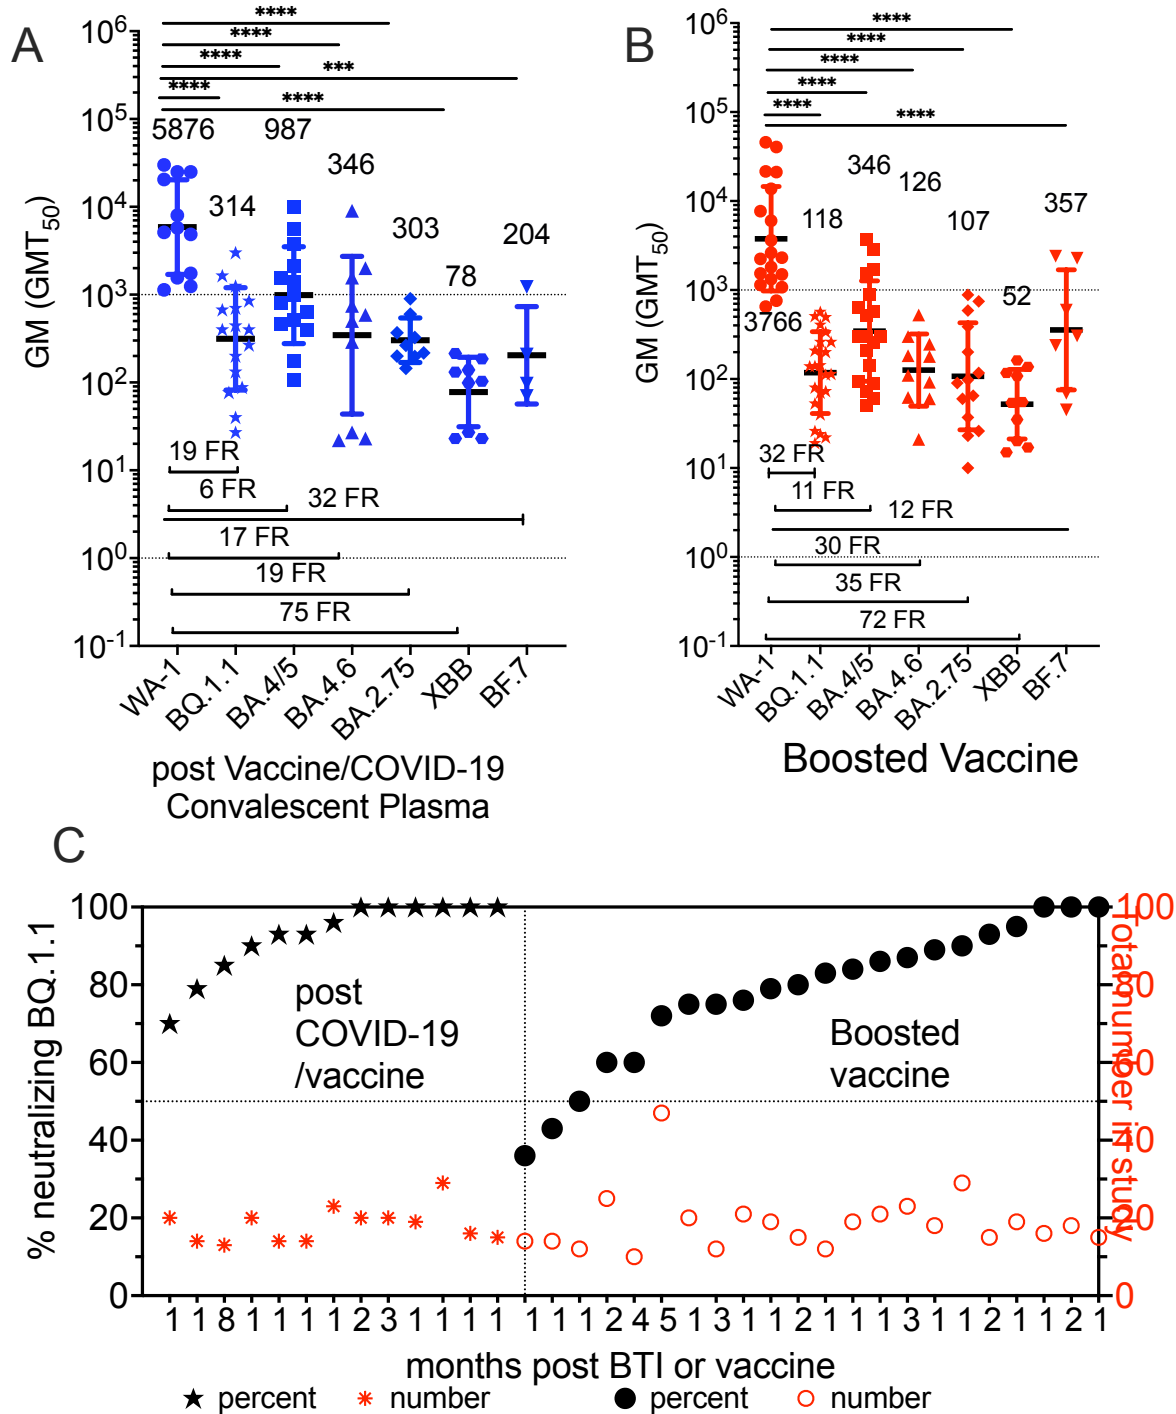

347 **Figure 1**
348 PRISMA flowchart for the current study. Number of records identified from various sources,
349 excluded by manual screening, found eligible and included according to subgroup analyses.
350

351

352 **Figure 2**

353 Neutralizing GMT (GMT₅₀) against WA-1, BQ.1.1, BA.4/5, BA.4.6, BA.2.75, XBB, BF.7. A) post boosted
 354 vaccinations and COVID-19 and B) boosted vaccinated plasma without COVID-19. Geometric standard
 355 deviation for error bars, fold reduction (FR) below data, and number of studies above x-axis. Geomeans
 356 statistically significant in difference by multiple comparison in Tukey's test are indicated. C) The percent
 357 of total samples within a study which neutralized Omicron BQ.1.1 graphed in increasing percentages on
 358 left y axis with the total number of samples tested on the right y axis.

359

360 **Figure 3**

361 Geometric mean neutralizing titers (GMT_{50}) against WA-1, BQ.1.1, BA.4/5, BA.4.6, BA.2.75, XBB, BF.7
 362 A) plasma Omicron infection alone or pre-boasted-6 to 11 months after last vaccine dose sampled in 2021
 363 or 2022. Geometric standard deviation for error bars, fold reduction (FR) above data, and number of studies
 364 above x-axis. GM (GMT_{50}) statistically significant in difference by multiple comparison in Tukey's test are
 365 indicated. B). The percent of total samples within a study which neutralized Omicron BQ.1.1 graphed in
 366 increasing percentages on left y-axis with the total number of samples tested on the right y-axis.

367

404

405 **Supplementary Figure 1**

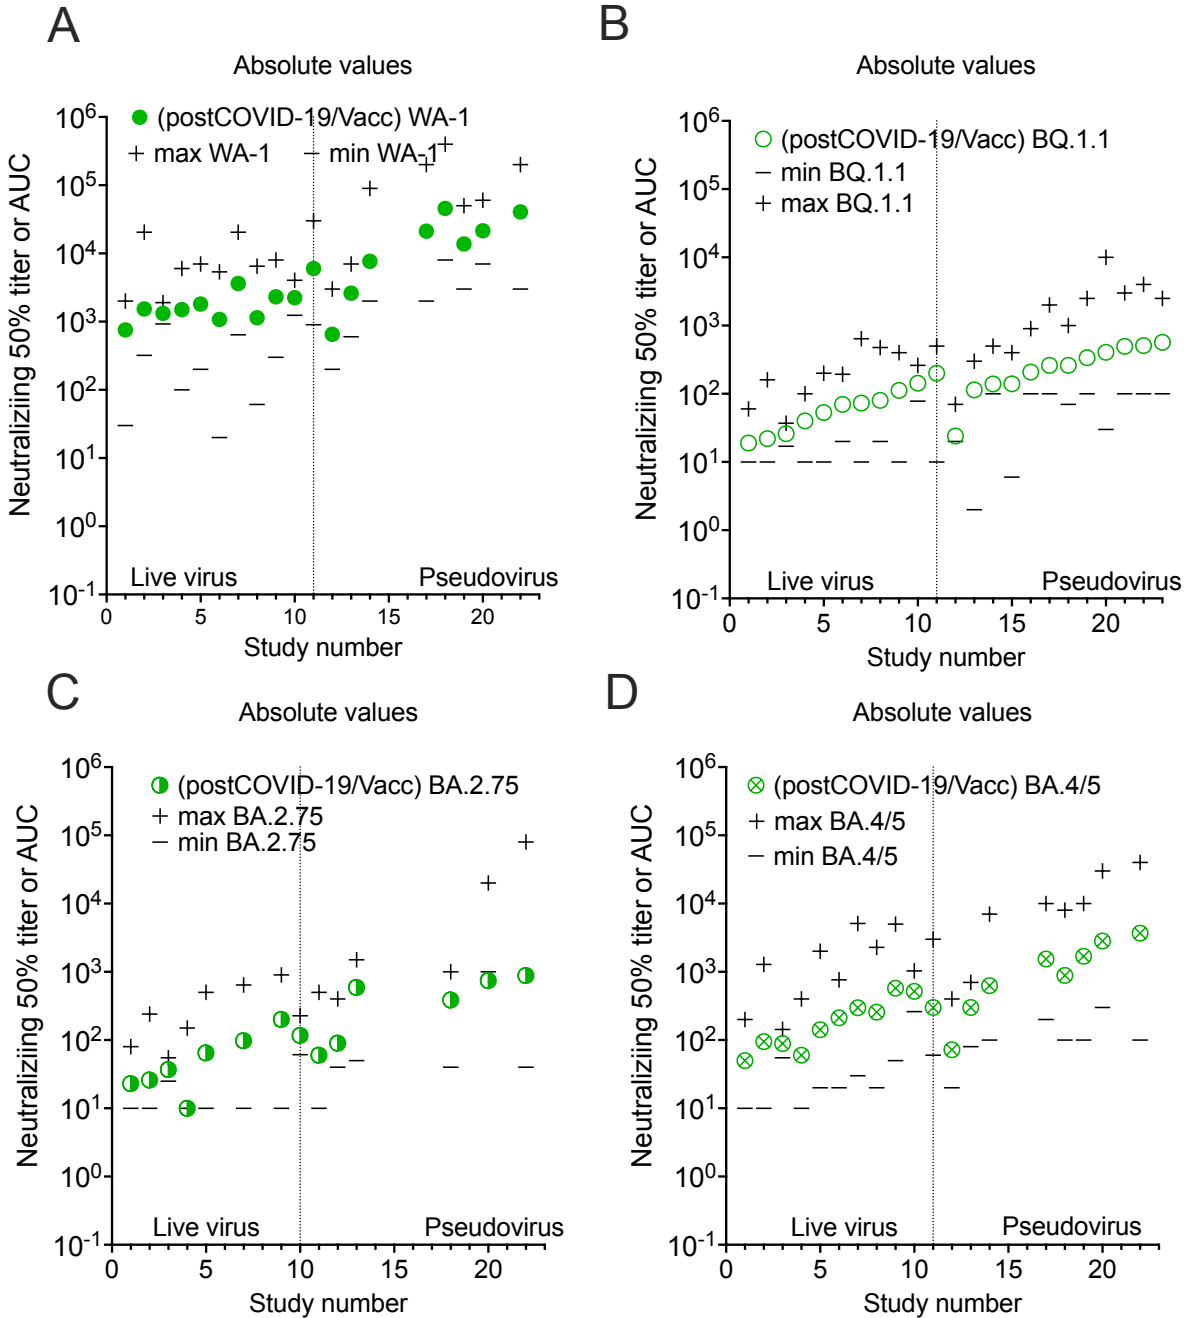

406 Plasma GMT₅₀ from post boosted vaccinations and COVID-19 sorted by study cohort with live virus
407 assays on the left and pseudovirus on right, with individual sample minimum and maximum
408 dilution titer also shown. A) WA-1; B) BQ.1.1; C) BA.2.75; D) BA.4/5.

411

412 Supplementary Figure 2

413 Plasma GMT₅₀ from boosted vaccinations only without COVID-19 sorted by study cohort with
414 live virus assays on the left and pseudovirus on right with with individual sample minimum and
415 maximum dilution titer also shown. A) WA-1; B) BQ.1.1; C) BA.2.75; and D) BA.4/5.

421

422 **Supplementary Figure 3**

423 Plasma GMT₅₀ from Omicron infection alone and also pre-boosted in 2021 or 2022 6 to 11 months
424 after last vaccine dose sampled sorted by study cohort with live virus assays on the left and
425 pseudovirus on right with minimum and maximum dilution titer also shown. A) WA-1; B) BQ.1.1;
426 C) BA.2.75; and D) BA.4/5.
